

From Cloud to IoT Device Authenticity under Kubernetes Management

George Kornaros, Dimitris Bakoyiannis, Othon Tomoutzoglou and Marcello Coppola

Intelligent Systems and Computer Architecture Lab – ISCA

Hellenic Mediterranean University, Heraklion, Crete, GR

The 11th International Conference on Internet of Things: Systems, Management and Security (IOTSMS 2024)
Malmö, Sweden. September 2-5, 2024

Outline

- Challenges and background
- Services security challenges
- SPIFFE/SPIRE technology overview
- FLUIDOS – KubeEdge and SPIFFE integration
- Demonstration
- Conclusion

Billion of Embedded Devices

ADAS & Autonomous Vehicles,
Cellular-V2X, connected cars

Secure anchors for Mobiles,
Industrial, Communications, IoT &
Edge nodes

Industrial & IoT Communication with IoT devices

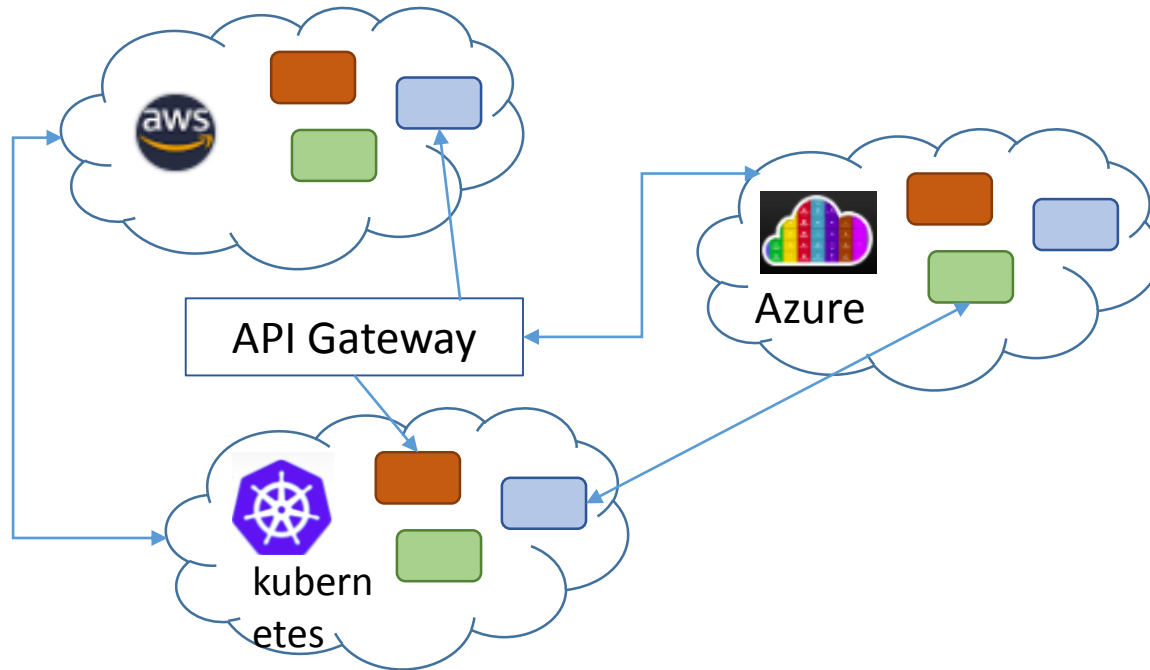

- Trust provisioning
- Secure element communication

Digital signatures

- Secure boot, Industrial & IoT Firmware integrity for IoT devices
- Over-the-air updates, Firmware authentication, smart car access

Exploding Cross-service Communication

A hacker gained access to 100 million Capital One credit card applications and accounts

By Rob McLean, CNN Business

Updated 5:17 PM ET, Tue July 30, 2019

MUST READ: Microsoft looks to turn the Web into a more collaborative canvas with Fluid Framework

Over 100,000 GitHub repos have leaked API or cryptographic keys

- Increased attack surface & risk of leakage across untrusted networks
- Long-lived service credentials exist across applications, repositories, platforms, and tools, making them ripe for theft.

Workloads Security Risks

- **Misconfigurations**: Improperly configured Kubernetes components can expose the cluster to attacks or unauthorized access.
- **Vulnerable container images**: Deploying containers with known vulnerabilities can lead to security breaches.
- **Insecure communication**: Lack of encryption and mutual authentication between services can result in data leaks and man-in-the-middle attacks.
- **Insider threats**: Malicious or negligent actions by employees or contractors can compromise the security of the container platform.
- **Supply chain attacks**: Infiltration of malicious code or compromised dependencies during the software development lifecycle can lead to compromised applications and infrastructure.

Authentication for Zero-Trust Security Model

Perimeter Security hard to defend when adding: Services, Clouds, Regions

Clouds and Containers Adopting Zero Trust

Perimeter - based

Zero Trust

Attempts to build a trusted “wall”

- Relies on IP addresses or physical locations
- Difficult to implement for today’s dynamic environments

Assumes “bad guys” are everywhere

- Uses cryptographic identities for authenticating every system/user
- Enables universal enforcement across hybrid infrastructures

SPIFFE Ensures Zero-Trust Security

Guarantee each workload/service will get its own SERVICE identity

- unique
- secure
- provable

SPIFFE

(Secure Production Identity Framework for Everyone)

- Challenge: have an identity, rotating secrets and automated bootstrap for trust and make it available for other systems to authenticate

Custom granularity

Can be fine grained as desired. Eg could be a specific process on a node.

Platform Agnostic

Not specific to any platform, doesn't assume eg k8s.

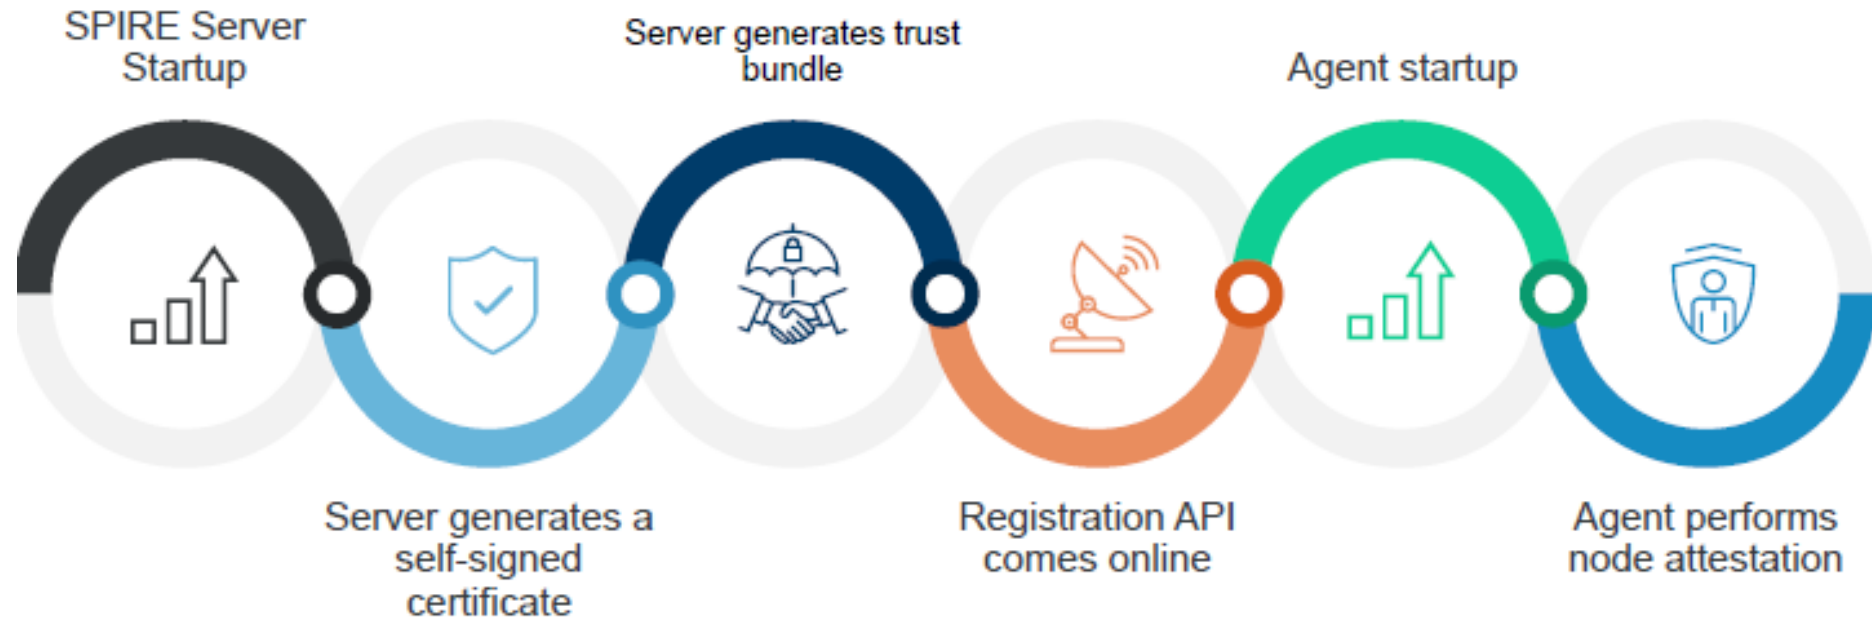

Elastic

A workload can span multiple nodes, each with unique IP addresses

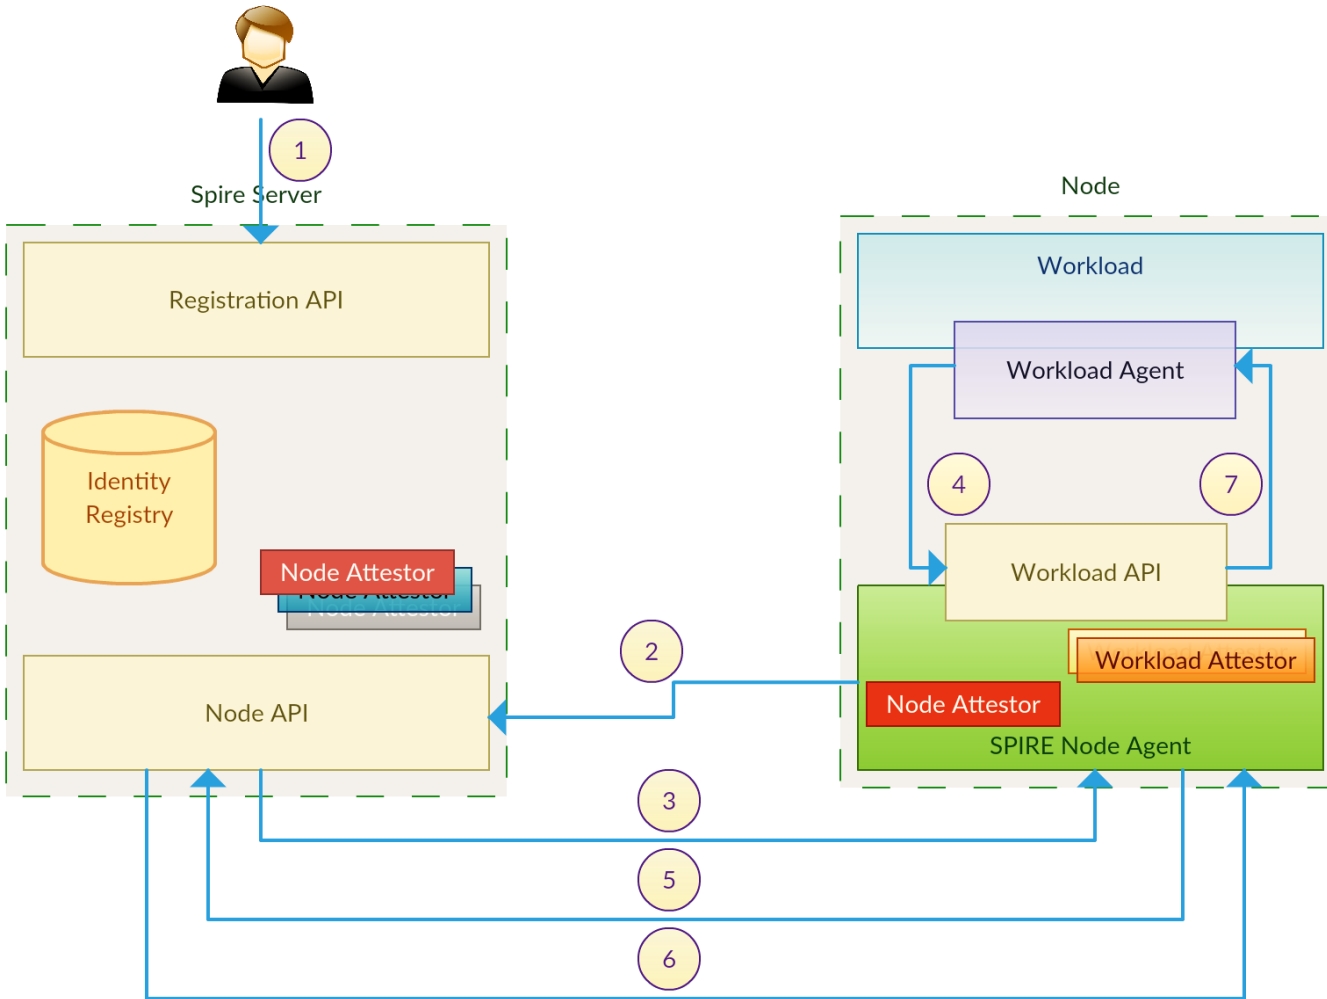

Isolated

Isolated from other workloads such that a malicious workload could not steal the credentials of another

SPIRE Server-Agent Startup

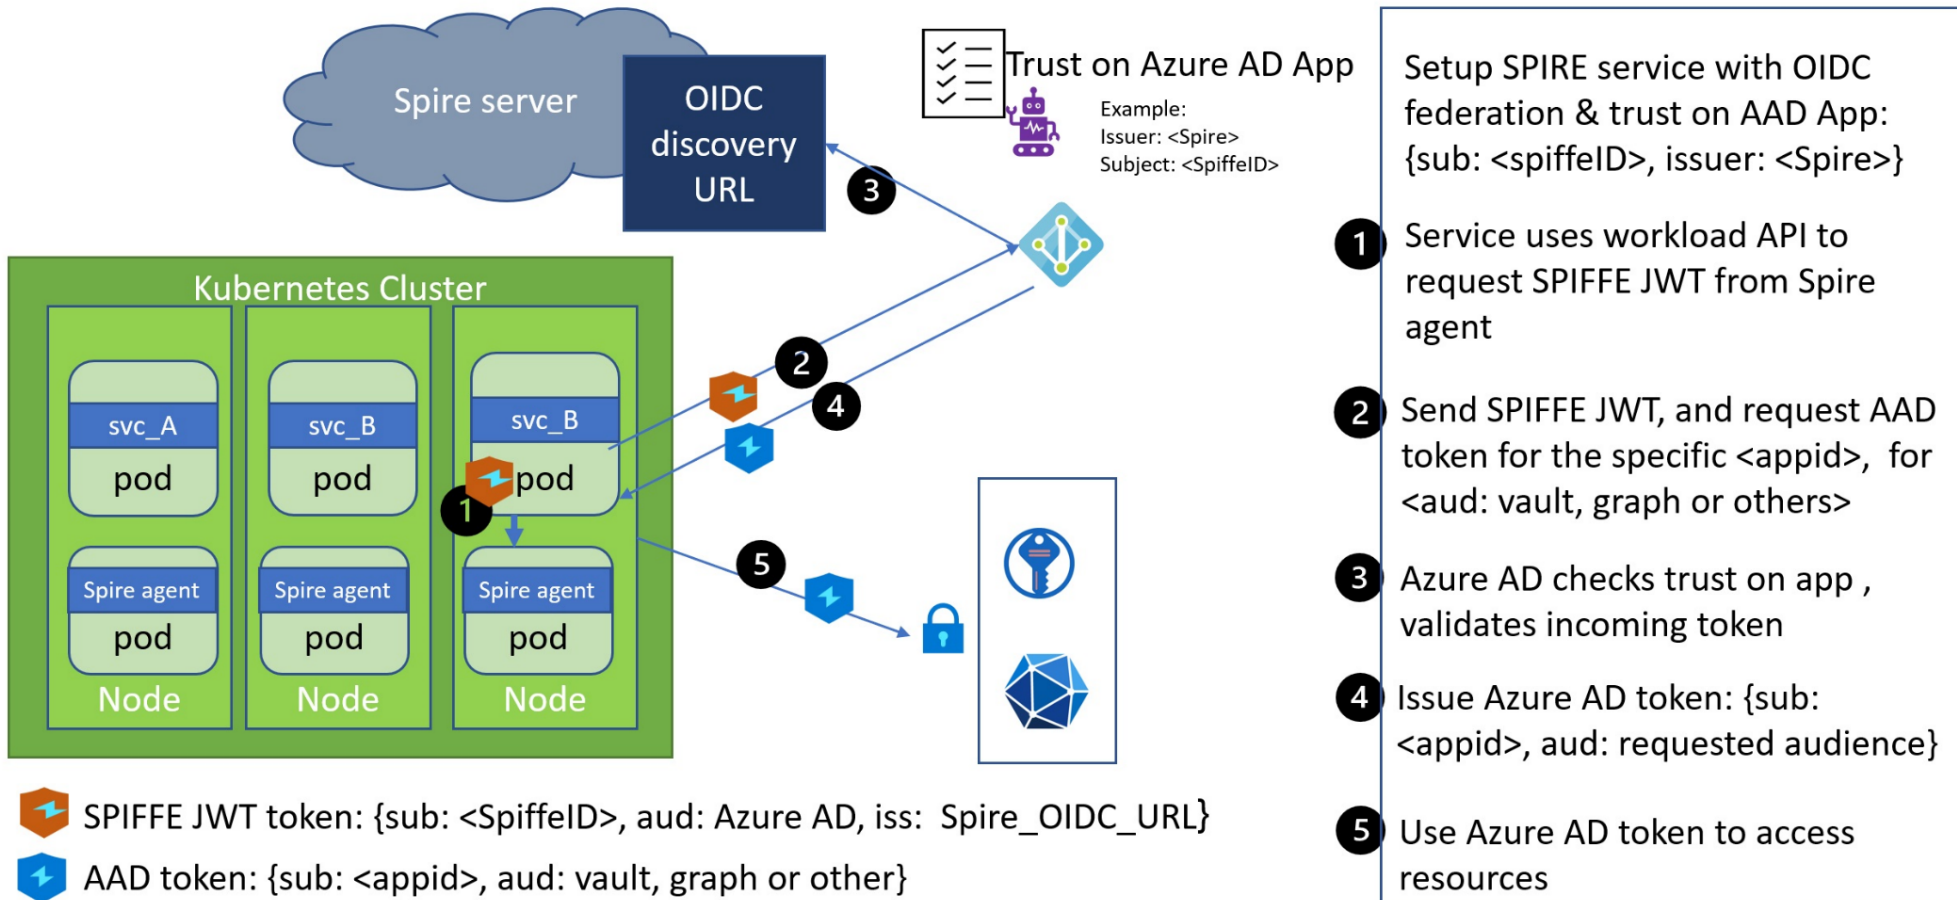

SPIFFE Overview

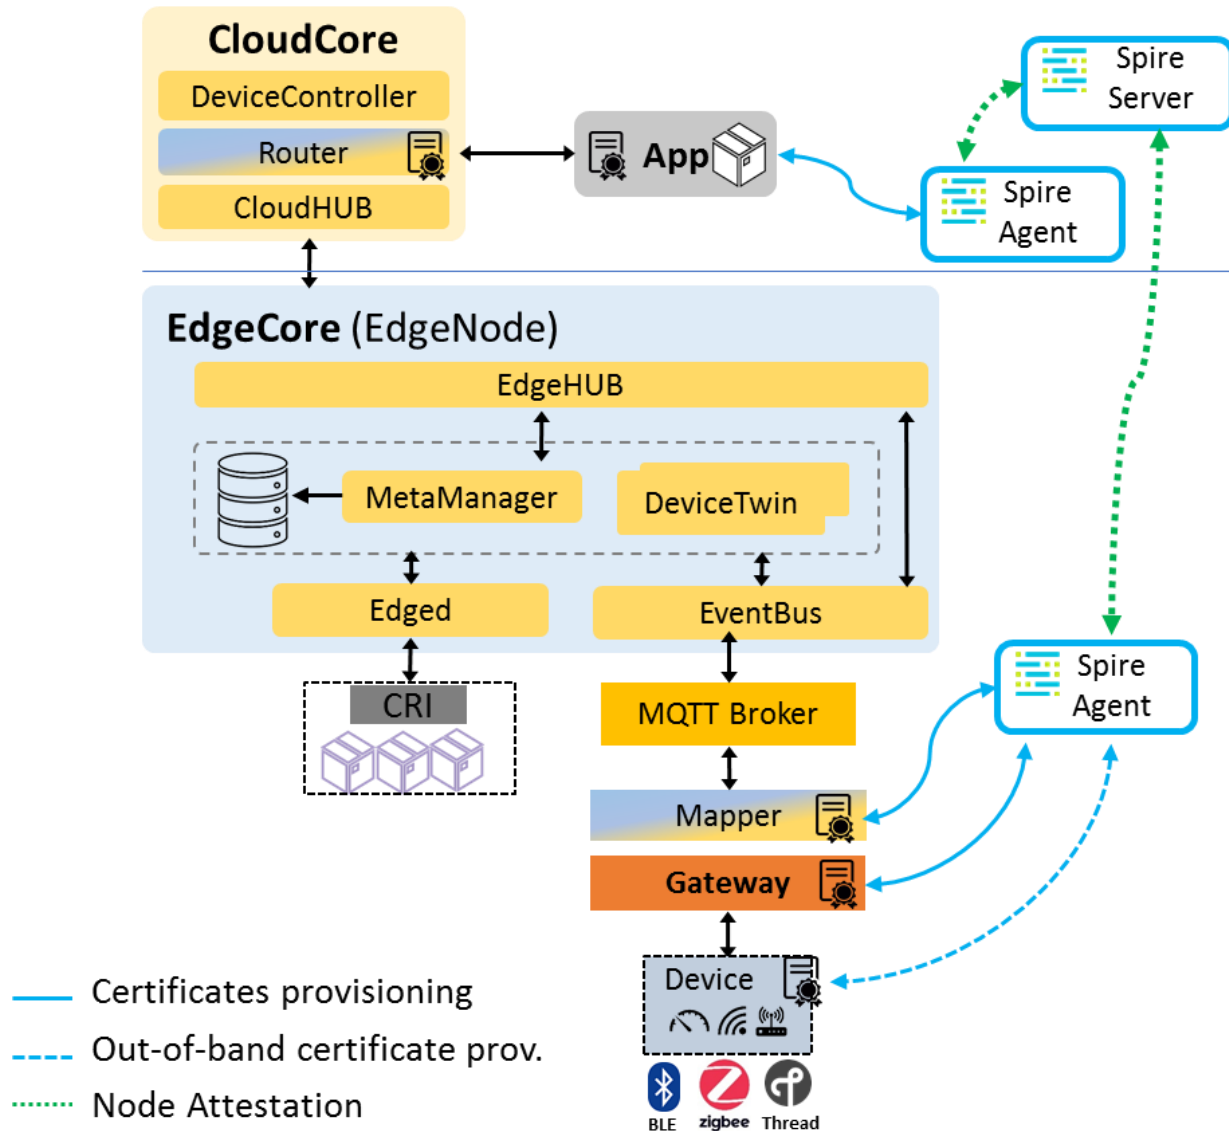

- Registration API is called by either an administrator or a third party application to populate the identity registry with the required SPIFFE IDs and relevant selectors.
- Node agent get authenticated with the SPIRE server using a pre-established cryptographic key pair or based in the infrastructure provider. For example in the case of AWS EC2, node agent will submit the node's Instance Identification Document(IID) issued by AWS.
- Node attesor in the SPIRE server validates the provided identification document based on the used mechanism. If the AWS IID is used, the relevant attesor will validate it with AWS settings. Upon successful validation SPIRE server sends back a set of SPIFFE IDs that can be issued to the node along with their process selector policies.
- When workload start to run in the node, it first make a call to the node agent asking 'who am I?'
- Based on the process selectors node agent received in the previous step, and using the workload attestors, agent decides on the SPIFFE ID to be given to workload. It generates a key pair based on that and sends the CSR(Certificate Signing Request) to the SPIRE server.
- SPIRE server responds to the node agent with the signed SVID for the workload along with the trust bundles, indicating which other loads can be trusted by this workload.
- Upon receiving the response from SPIRE server, node agent, handover the received SVID, trust bundles the generated private key to the workload. This private key never leave the node it's workload belongs to.

Example: Azure AD workload identity federation with SPIFFE and SPIRE

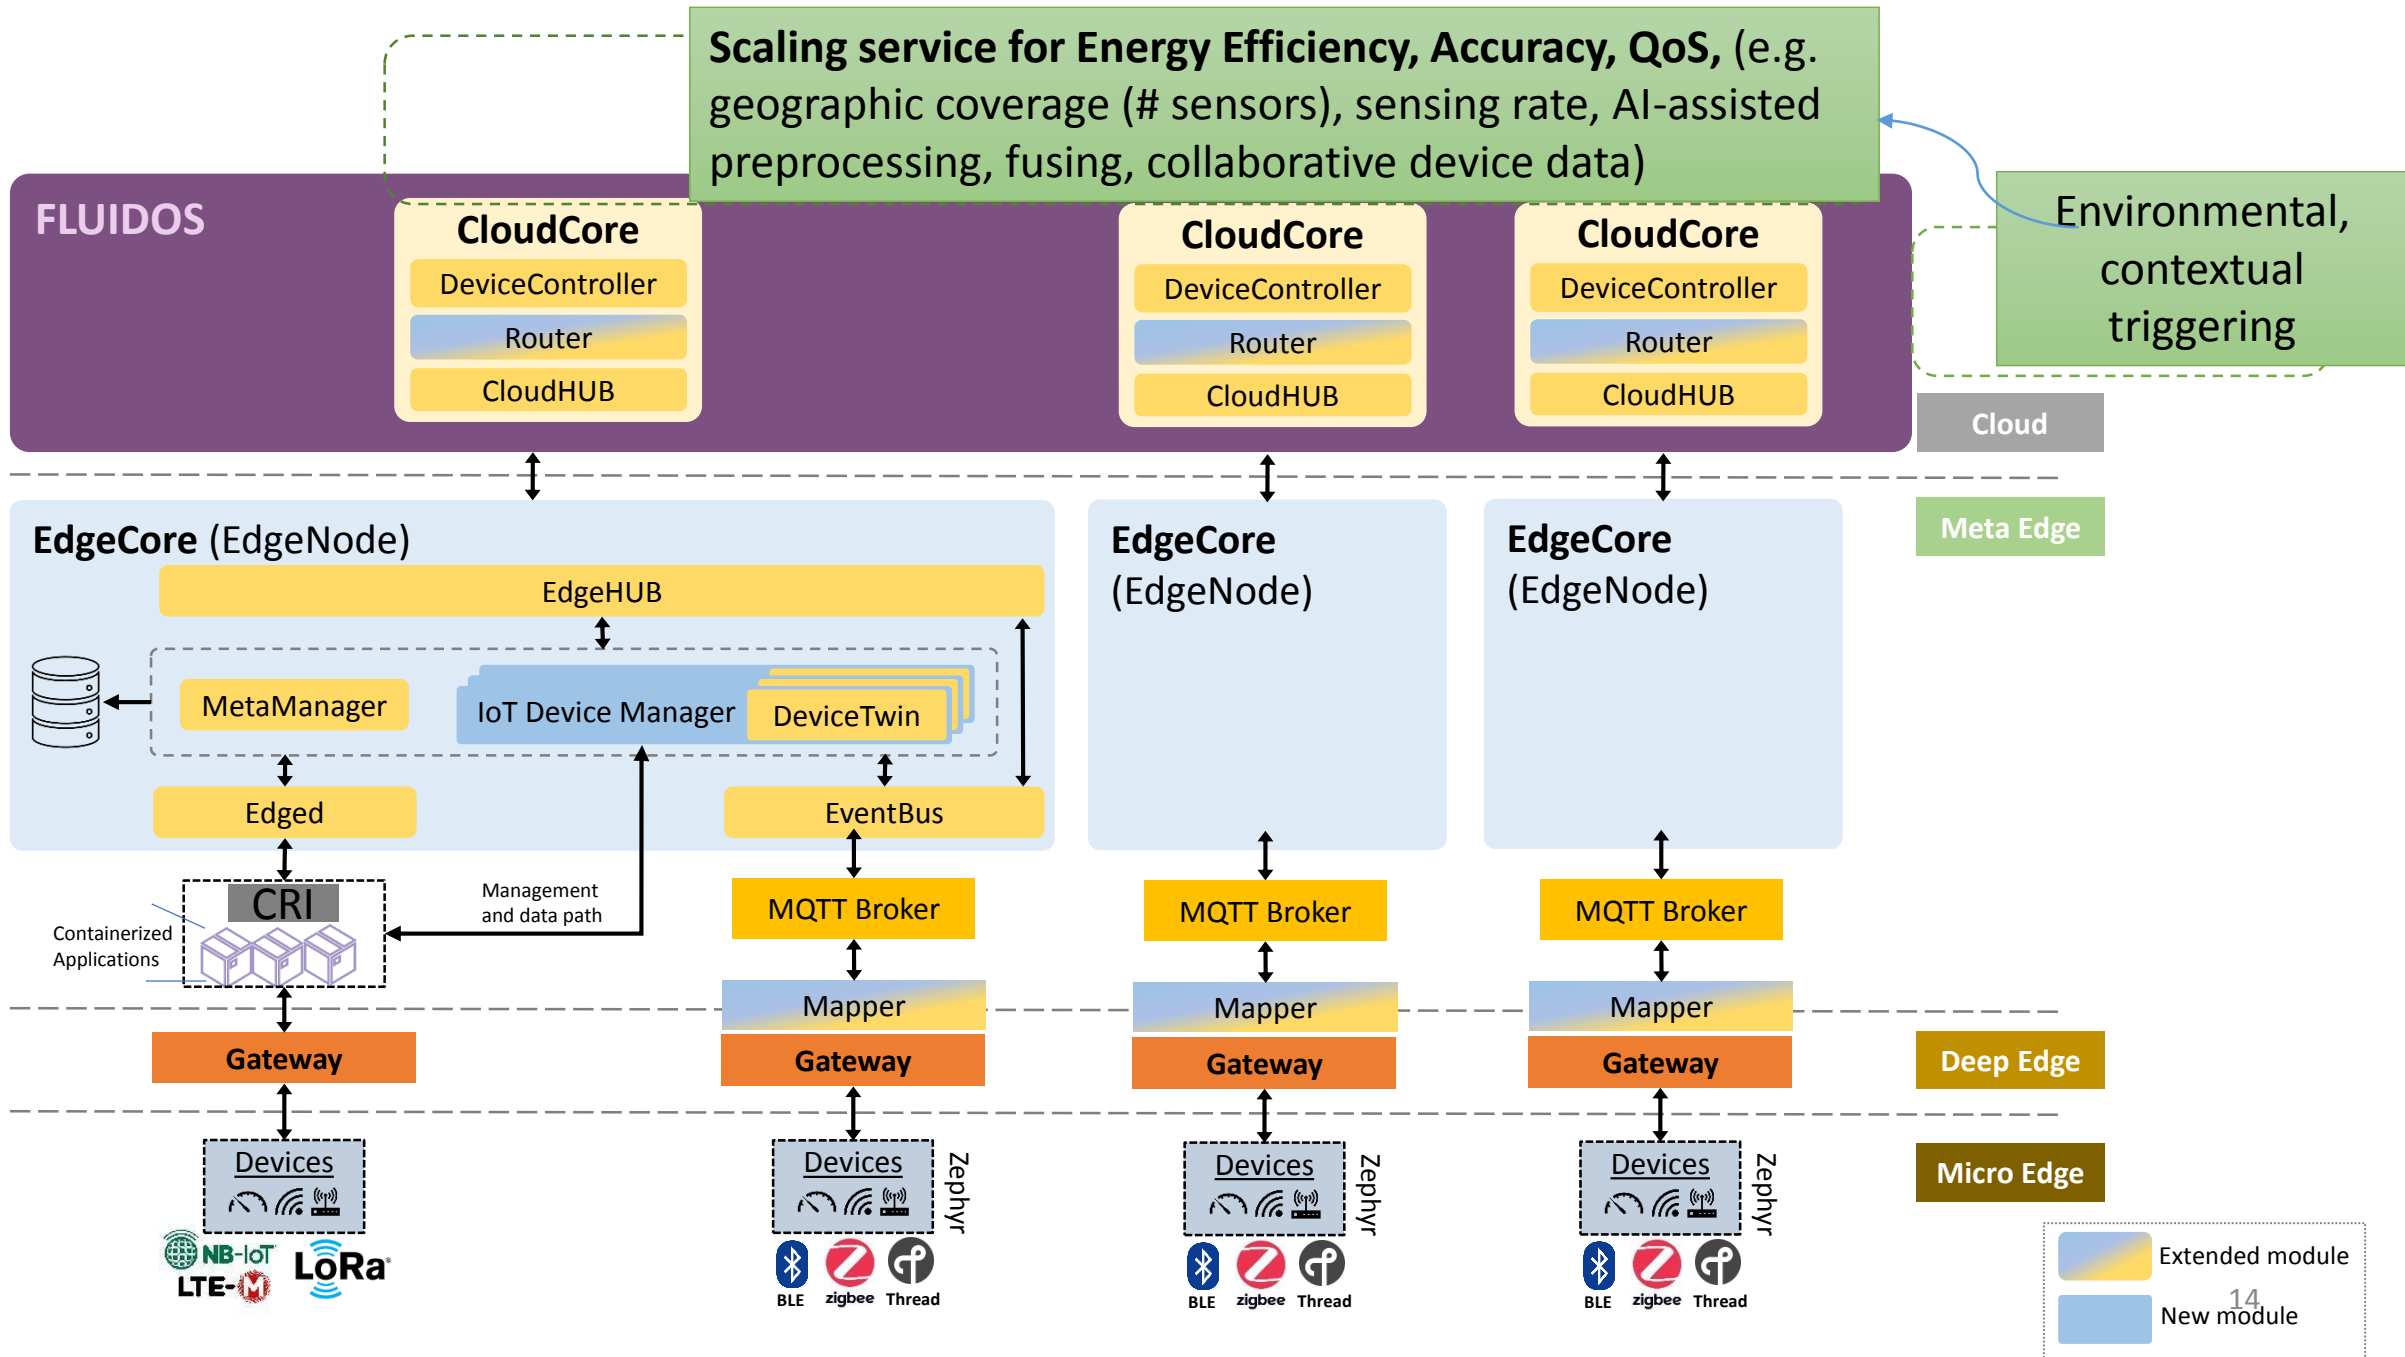

Azure AD tokens using SPIFFE JWT

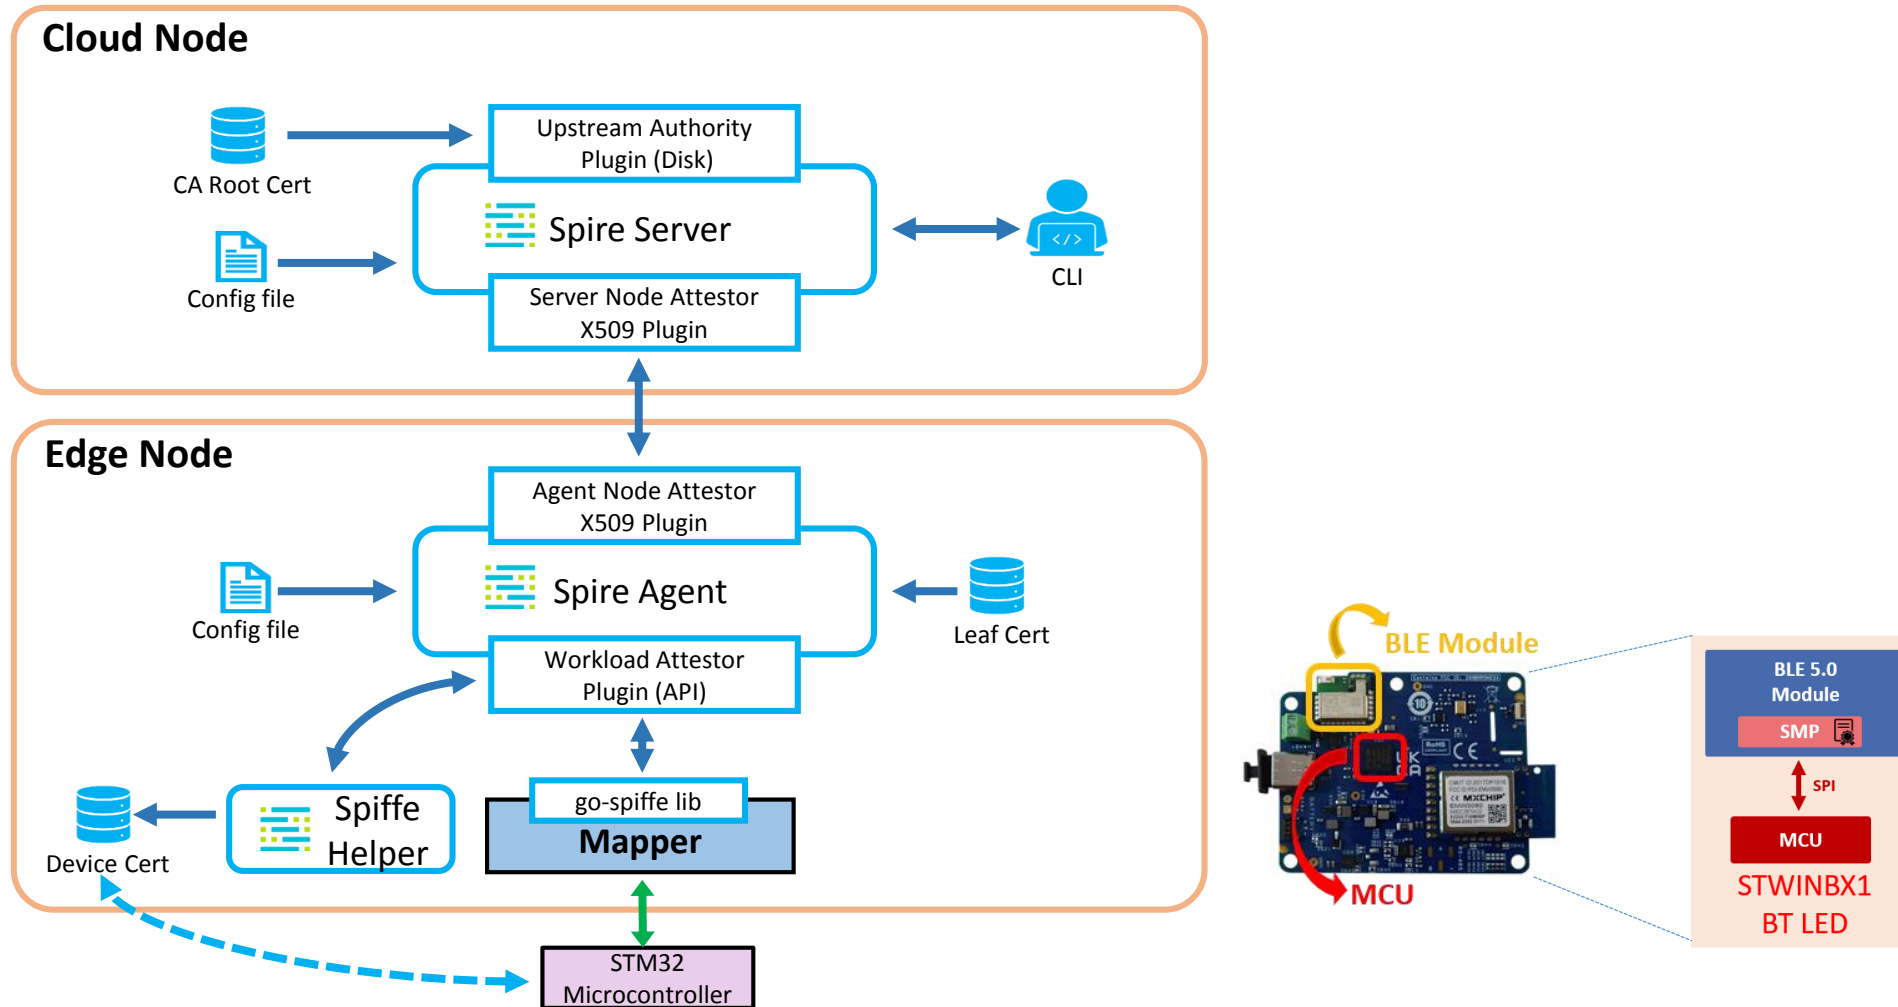

SPIFFE in IoT-Edge Architecture (FLUIDOS)

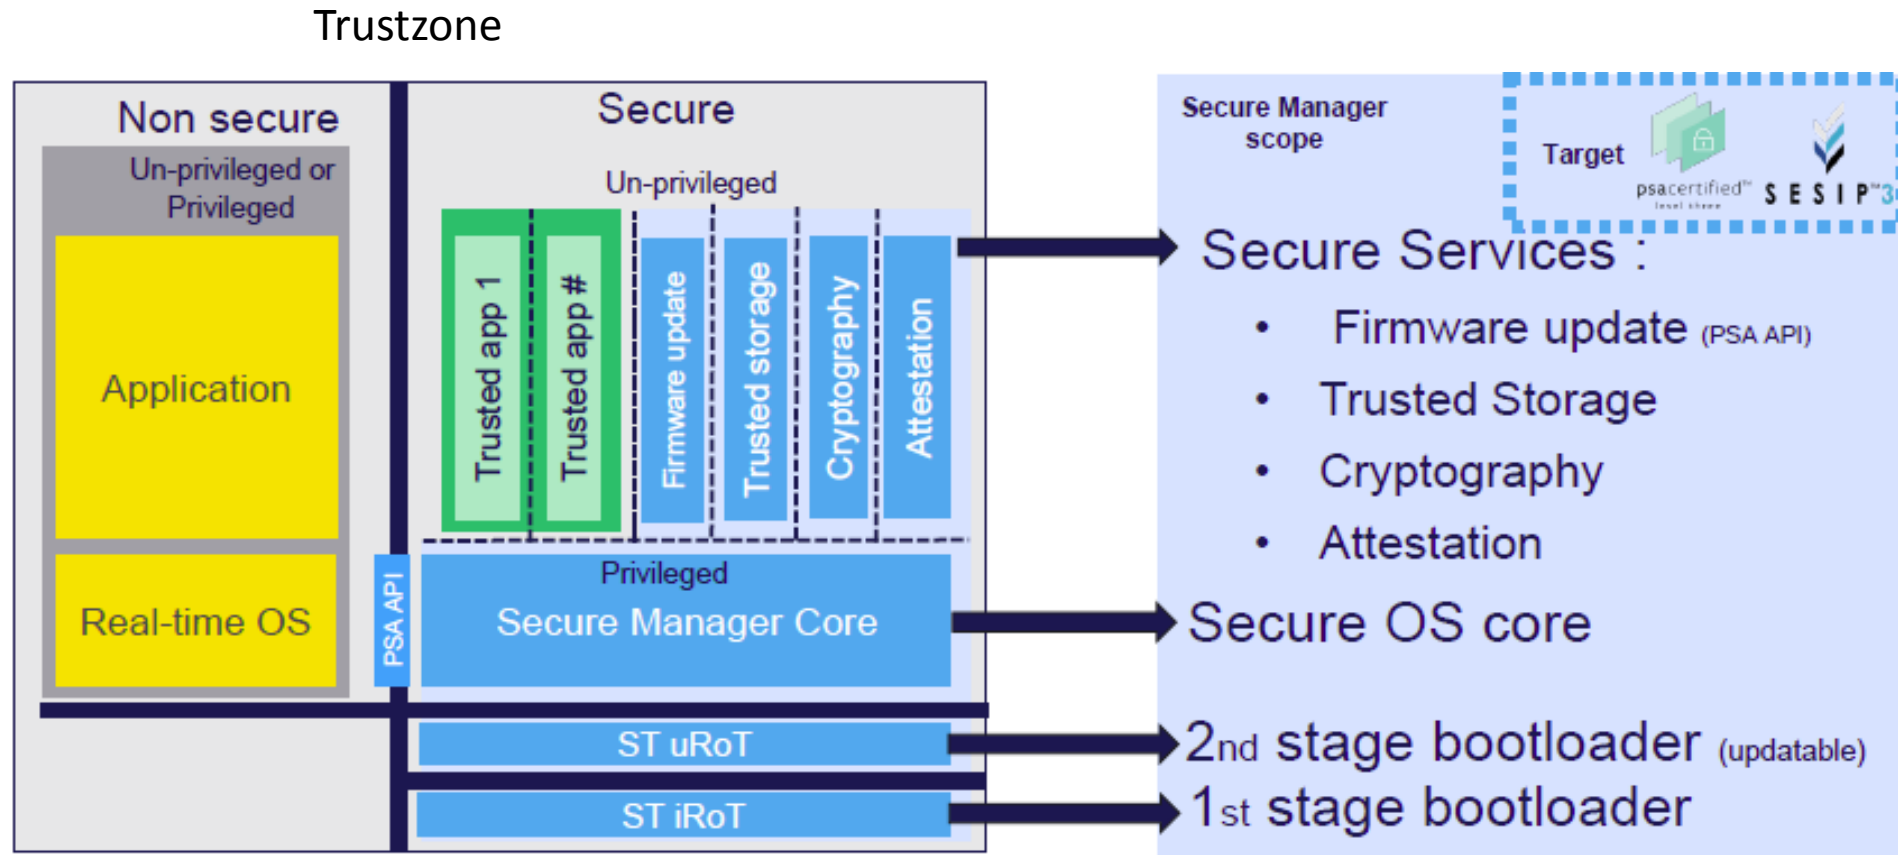

- **Cloudcore-EdgeCore** monitoring resource changes
 - Metadata traffic includes edge node status and application status
- Extended Kubernetes **Custom Resource Definitions (CRDs)** to manage sensor data traffic

IoT Device Identity Provisioning

Secure Device Management

Securing BT STWINBX1 – Mapper Communication

BLE Stack and Secure Communication:

- BLE stack integrated - in the GO BLE Library and the BLE Module
- BLE stack integrates the Secure Manager (SMP) to enable Secure Connections
- Mapper and BLE Module use Diffie-Hellman handshake to secure connection
- Diffie-Hellman requires certificates in both sides provided by Spire Agent

1. Mapper:

- Attest to the Spire Agent and receive certificate
- Enable BLE Secure Connections (through SMP)
- Provide the certificate to the SMP to start Diffie-Hellman secure pairing

2. Spiffe Helper:

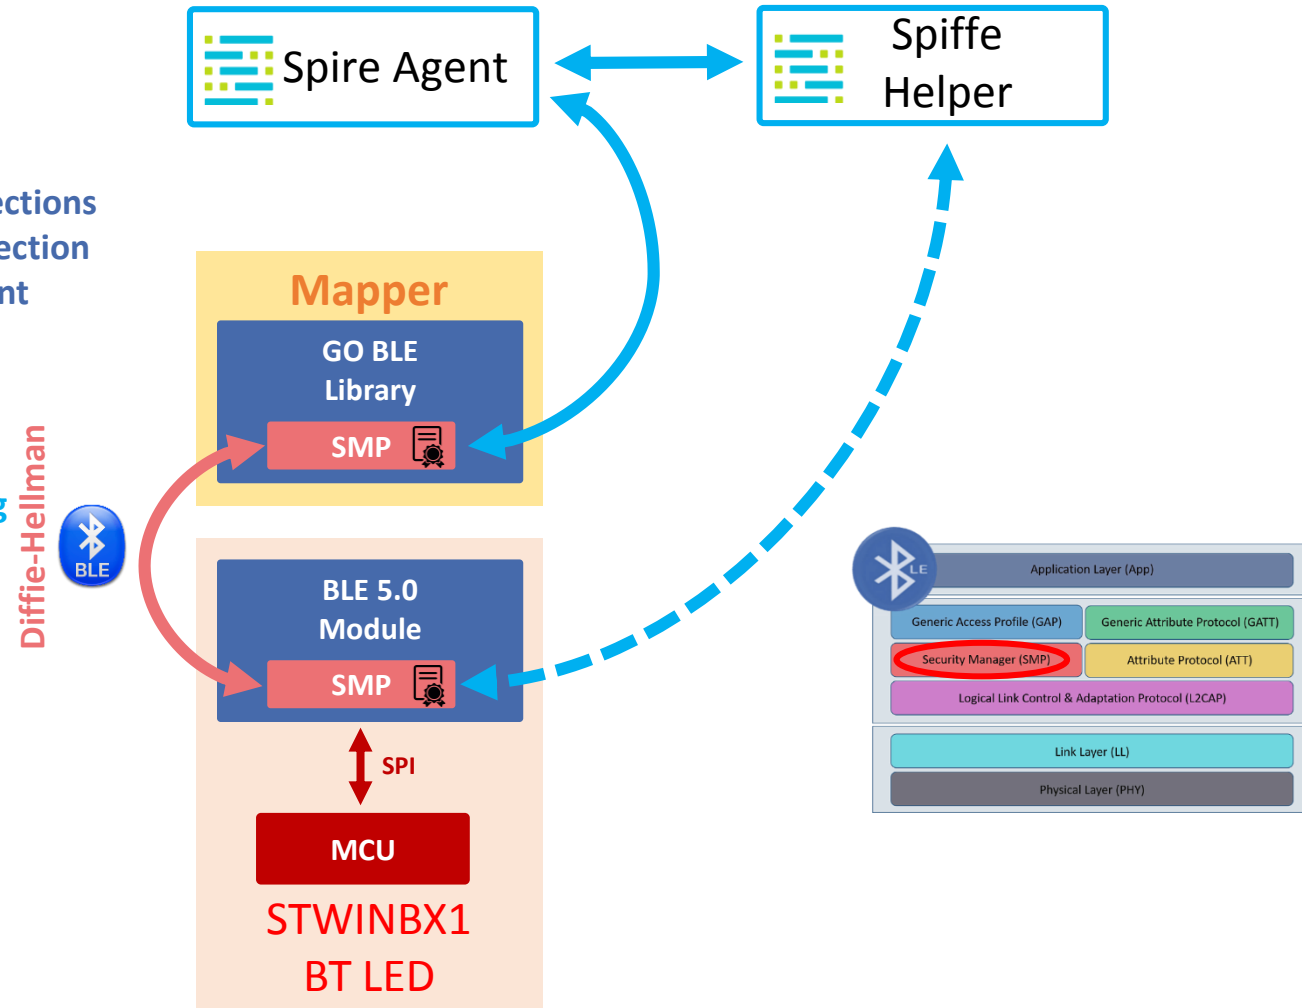

- Run attestation on behalf of the BT LED
- Receive certificate on behalf of the BT LED
- Out-of-band distribution of the certificate to the BT LED

3. STWINBX1 MCU:

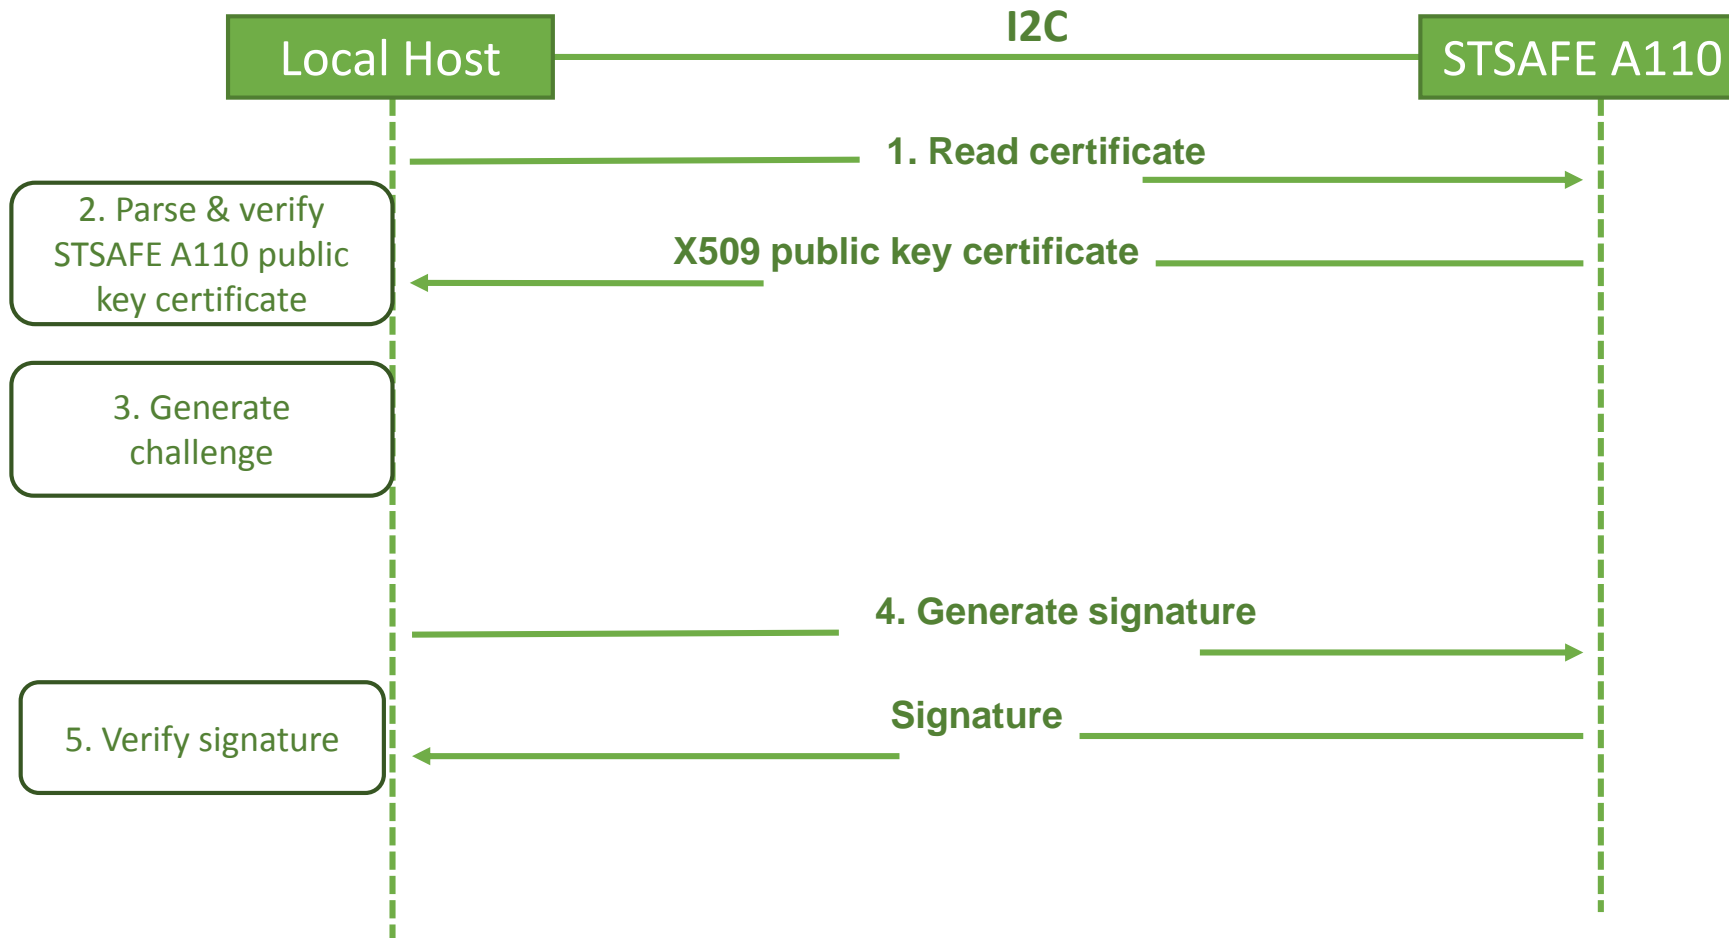

- Configure the BLE Module to enable BLE Secure Connections (over SPI)
- Provide the BT LED certificate to the BLE Module (over SPI)

———— Spire certificate distribution/attestation

- - - - - Out-of-band certificate distribution

Secure Device Bootstrapping

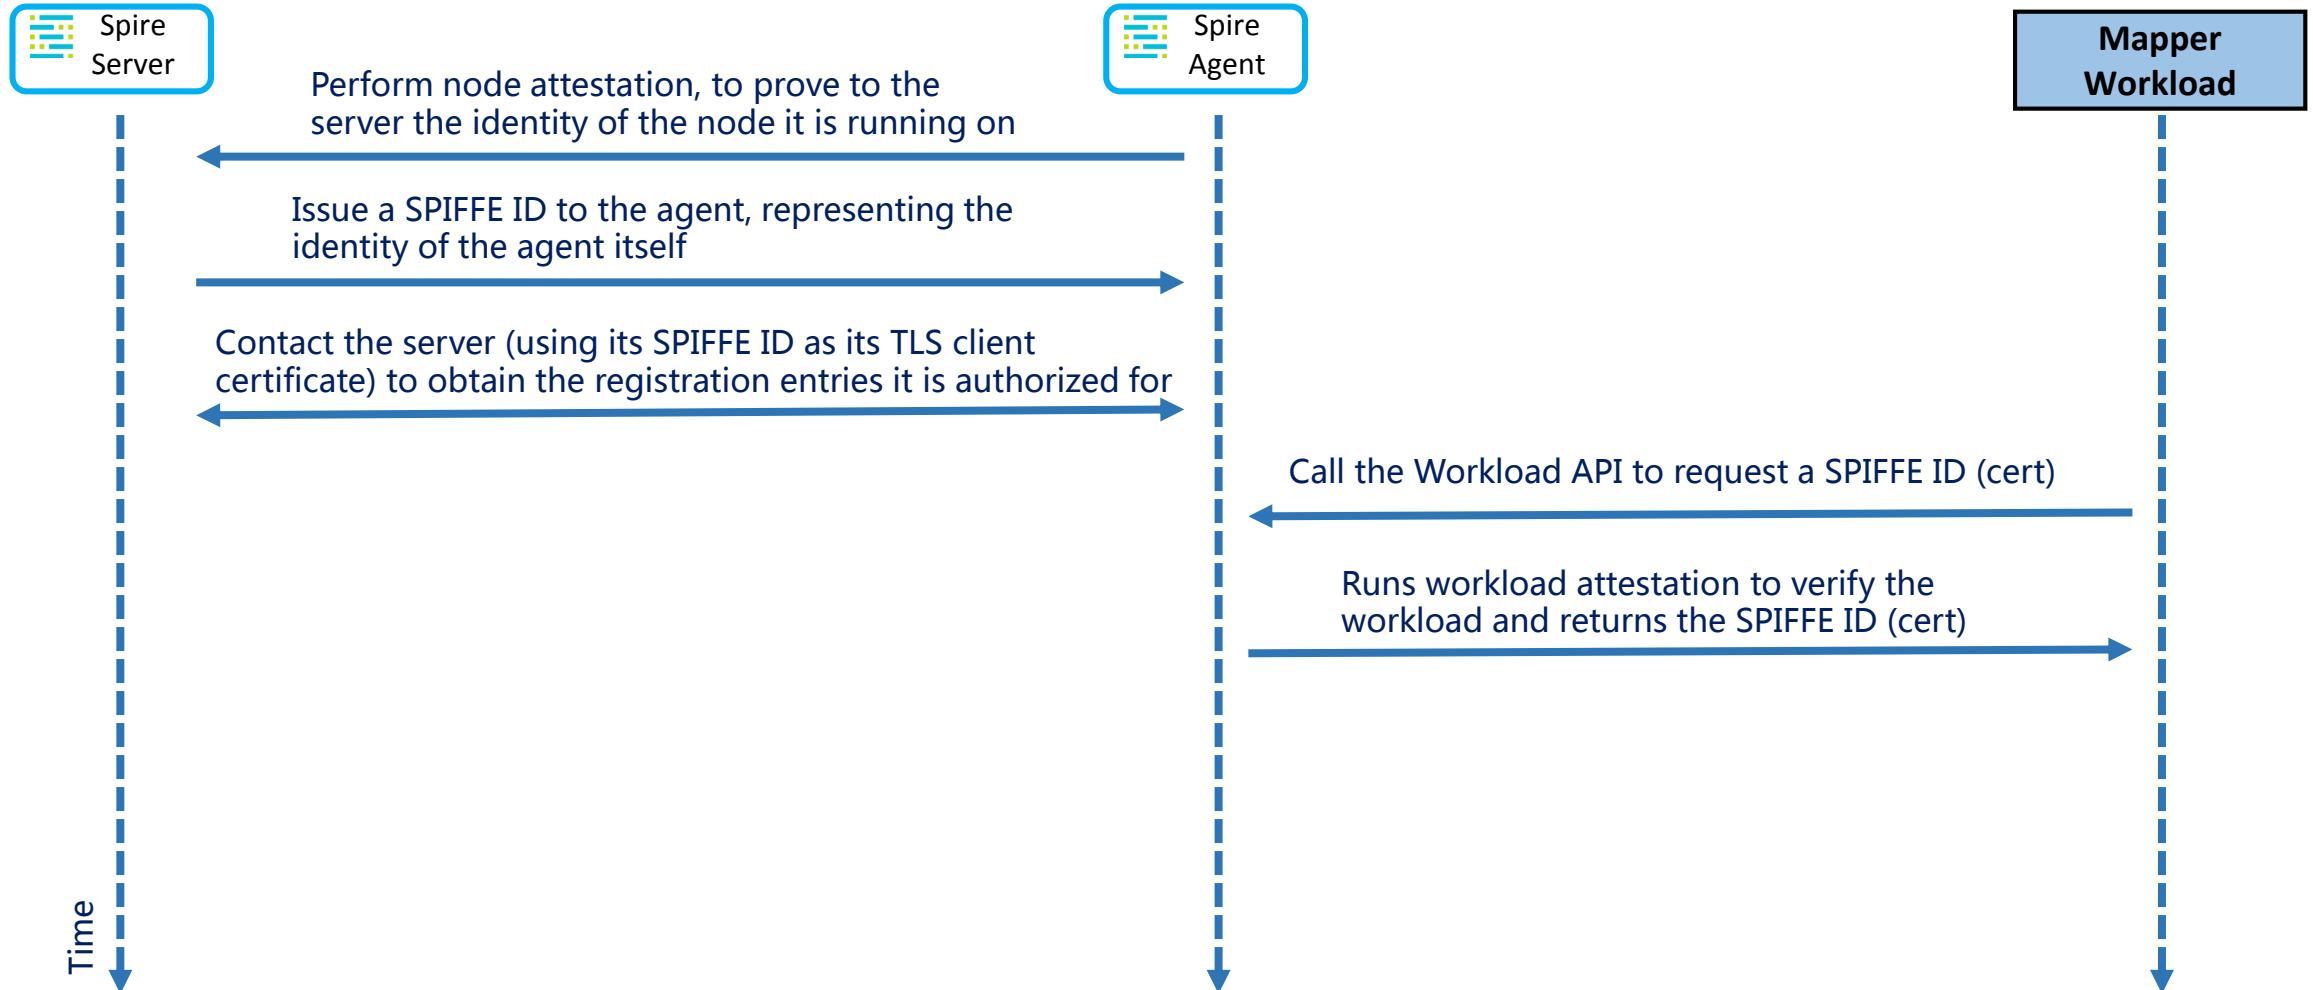

- **Threats**

- Device cloning or counterfeiting
- Device integrity or data corruption

- **Countermeasures**

- EAL5+ CC certified secure MCU
- Secure operating system, secure handling of cryptographic keys
- Customer secure keys and certificates loading at ST in a security certified environment

Mapper Identity Provisioning

Certificate Distribution to Mapper

The image shows a terminal window with three distinct sections, each with a title and a corresponding icon in the top right corner.

- Registering the Mapper workload to the Spire Server** (CLI icon): This section shows a terminal window with a black background and yellow text. The terminal output consists of a series of log messages from the 'spire-server.service' on 'kcloud' at '2024-04-29T10:30:02+03:00'. The logs include a warning about 'umask 0022', followed by information about opening and initializing a SQLite3 database, loading several plugins (disk, KeyManager, NodeAttestor), and preparing an X509 CA. The terminal ends with 'lines 318-328/328 (END)'. A 'CLI' icon is in the top right.
- Starting the Spire Agent** (Spire Server icon): This section shows a terminal window with a black background and yellow text. The terminal output is currently empty, with the prompt 'kedge@kedge: ~\$'. A 'Spire Server' icon is in the top right.
- Attempting to attest the BLE Mapper to the Spire Agent** (Mapper icon): This section shows a terminal window with a black background and yellow text. The terminal output contains the following text:
Attestation failed because the Mapper is not registered to the Spire Server
Re-attempting to attest the BLE Mapper to the Spire Agent
Mapper workload successfully attested and received X509 certificate
Mapper continues normal operation pairing with the BLE device and receiving data
A 'Mapper' icon is in the top right.

Conclusions

- SPIFFE identity management and mTLS based connectivity for trusting Sensor-generated traffic flows in a the Kubernetes-managed cloud-edge setup
- SPIRE's plugin architecture enables diverse workload attestation options beyond the Kubernetes namespace and service account attestation (e.g., offered by Istio)
- Holistic Identity management in IoT-based environment
- SPIFFE and the service mesh ecosystem are the technology I wish the virtualization, networking, and security vendors had built 5-10 years ago...
